Overview

PSP uses 2 databases (Monolith & Audit/IBOB). Currently as part of Oracle Exit workflow testing, we are using standalone database (restored from snapshot of replicated database from Oracle). As part of testing, we would need to refresh this standalone database multiple times.

Problem Statement

- Keeping size of database in mind, we need to figure out right and optimised approach for this.
- Automate approach once its finalised.
- Ensure reduced time, efforts & cost optimisation.

Goal

- Refresh database with latest data to test workflows.
- Single click/script automation.

Benefits

- Quickly enable latest data for workflows to test and unblock team.

Approaches

	Approach	Pros	Cons	
1	Point In Time Restore	• less time in execution • Complexity	• 1 day less data would be available	
2	Snapshot Restore	• less time in execution • Complexity • latest (5-10 mins less data) data can be available		
3	Incremental Refresh		• take more time as compare to above approaches • Complex in terms of getting exact LSN and storage consumption • setup DMS replication accordingly	

Implementation
