

Oracle Active Data Guard between IHP and AWS for PSP

Created by Choubey, Mayank, last modified by Popat, Ketan Gunvantrai on Jun 28, 2019

About Active Data Guard

Oracle Active Data Guard delivers near real-time data protection and availability by maintaining a synchronized physical replica of a production database at a remote location.

Scope

This solution of Oracle Active Data Guard is Plan-B for PSP AWS migration.

As per Plan-A, we are going to run PSP on AWS RDS for couple of regular business days. We would be analyzing operability, stability and performance matrices with all the stack holders. In case if we foresee any risk which could lead to a need of rollback while running it on peak business day, we would like to exercise this Plan B in favor of minimizing downtime. The benefit of Plan-B is, as it replicates the data using block-to-block methodology it ensures the lag within 60 secs. Where as going by lag history of Plan-A, Oracle GoldenGate replication lag could go upto 10 hours.

Since we are planning to exercise Active Data Guard option max for 2-3 weeks, we have made a very conscious decision to accept that database and backups in IHP would be used for high availability, disaster recovery and backup in case if need arises.

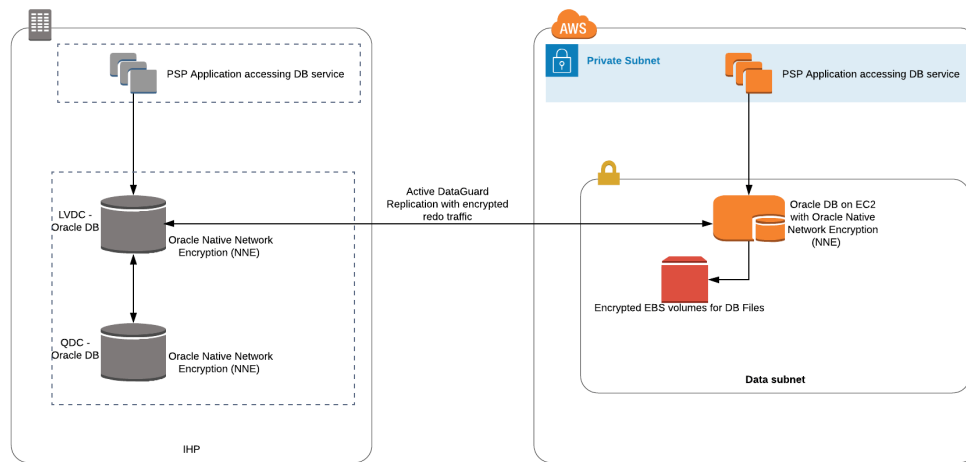

Setup

PSP application make use of 2 database - Monolith and IBOB.

This document describes the database replication setup via Active DataGuard between IHP and AWS.

In IHP, we already have ADG between QDC and LVDC. Further we added one more replica of same in AWS.
